

EFFECT OF VARIOUS TRANSACTIONS IN COTTON AND ACCOMPANYING BRUSH

DALIA SALIM ALKUTUBI, SHAKER MAHDY SALEH & RAMADAN ALTAYAF

Baghdad University

ABSTRACT

The experiment of this study was applied in 1999 in a field 12 kilometers northeast of the city of Tikrit to study the effect of three types of selectivity herbicides on the number of grass weeds and their growth that accompany the growth of cotton, specially on Johnson grass and purple panic grass using two different concentrations for each one with two dates of spray.

We use factorial experiment by randomized completer block design with four block. Every block contains 12 treatments in addition to the control treatment. The herbicides which we used were focus ultra, fusillade super, gallant super. Every herbicide applied by two concentration (2,3 L / h) for cycloxidim and (0.75, 1.5 L / h) for gallant super and fusillade super with two dates of spray. The first one was in 18th June and the second was in 10th July.

KEYWORDS: Transactions, Cotton, Accompanying Brush

INTRODUCTION

The cotton seeds of Ashor variety was planted on 26th of April 1999 in silt clay loam. Using the method of planting on lines with 90 cm between them. The seeds were planted in holes with 25 cm distance between each and the following one. The amount of seeds were 4 kg / d. the soil was fertilized by DAP fertilizer with average of 70-100 kg/d. The results of use of herbicides with different concentrations respectively by different date of spray was lead to increase the yield of cotton with average. The effect of weeds decreased on the growth of cotton plant by the use of focus ultra compared with gallant super and fusillade super.

Properties of vegetative growth (number of vegetative branches, number of fruit branches, number of nodes until the first fruit branch, number of the bolls, number of weeds , the weight of dry weed plants) were effected, specially when we use focus ultra by lower concentration and by early data, which show clear effect on weeds growth and cotton growth.

We have done a secondary experiment to know the effect if any, on the plant crops after cotton in the same soil. We applied the experiment in small containers, every container represents the soil of experimental unit. After fertilized all containers planted the wheat and notice some property of the wheat analyzed the results and we found that the focus ultra herbicide lead to increase in the average for ratio of wheat emergence 99.5% and thus we found that focus ultra is the best and does not stay in the soil for long. Hence it make less pollution.

MATERIALS AND METHODS

Applied this experience in the season of 1999 in a field located in the Samra district, 12 km north-east of Tikrit. As six samples were taken from the soil of the field from different locations and a depth of 30 cm to study the physical and chemical characteristics of the soil were analyzed in the laboratories of the General Establishment for Research on soil and water resources of the Ministry of Irrigation. Three factors were studied in the experiment. The first factor represents three types of pesticides namely Super Kalnt and Faozlaad Super and Ultra Fox. The second factor was the focus factor as Use

of each pesticide of the three pesticides (0.75 and 1.5 liter ha) the Kalnt Super and Super Faozlaad. The Ultra is Fox (2 and 3 liters hectares).

Winning Recipes and Ingredients

Germination Rate: The character was taken 5-15 rate ratio of 1999 when an account for germination rate of the field was germination for all treatment units 98. 517%. The average germination rate of control transactions is 98. 5%.

Plant Height in the Early Stages of Growth: The character was taken 6/16/99

The Number of Nodes up to the First Branch Fruit: The character was taken 09/09/99

Fruiting Branches: The character was taken 8/23/99

Number of Branches Vegetative: The character was taken 8/23/99

Number of High-Bush Plants Securities before Applying Transactions: The character was taken 6/15/99

Number of High-Bush Plants Securities after Applying Transactions: The character was taken 02/07/99 and also 24/07/99

Dry Weight of the Jungle: The character was taken 9/11/99

The number of days on agriculture and very open first flower

The number of days on agriculture up to 50% of the open flowers

The number of days on agriculture and very open first nut

The number of days on agriculture up to 50% of the open walnuts

Experience the Residual Impact of Pesticides on the Crop Cotton Deserves

Experiment was conducted to determine the residual impact of pesticides applied in the first experiment to yield the most entitled to cotton, a crop of wheat and conducted the experiment in Snadin of 20 cm diameter of the upper base. Lower and base diameter 14 cm and, Length Sindana 19 cm. As the situation in each soil Sindanh represent experimental unit transactions represent experience Previous soil taken from the land of cotton field planted earlier and applied to it the previous transactions as put a length of 16 cm soil was fertilized with nitrogen and phosphate fertilizers according to the recommended quantities of wheat. Anvils planted in 11.25.99 as Anvils seeds planted wheat class Abu Ghraib at a rate of 10 seeds in Sindana then told Anvils immediately after agriculture. Continued irrigation every 10-14 days following characteristics were calculated:

Germination rate

Plant height at vegetative growth stage

Number of forest per plant

The results of the experiment were analyzed statistically according to complete randomized block design and test the moral test by Duncan multi border.

RESULTS

DISCUSSIONS

Analysis of variance table refers to the number of nodes recipe for very first branch to a highly significant statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment. Table 4 Special arithmetic averages is clear that the use of pesticides has led to an increase in the number of nodes was significantly compared with the treatment that did not use the pesticide.

Statistical analysis of the number of fruiting branches recipe indicates the statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment. Table 5 shows that the use of pesticides has led to a highly significant increase in the number of fruiting branches.

Special analysis of variance in the number of vegetative branches shows a highly significant statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment. Table 6 shows that the use of pesticides led to the small number of vegetative branches.

Analysis of variance table refers to the number of days from the recipe on agriculture up to 50% of flowering to the presence of highly significant statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment. Table 9 shows that the use of pesticides has led to a lack of the average number of days to 50% flowering compared with treatment that did not use the pesticide.

Evidenced by the analysis of variance table to the presence of highly significant differences between the arithmetic mean of the number of days recipe for up to 50% of flowering resulting from the use of different types of pesticides has led the use of the pesticide Fox Ultra low in the arithmetic average of the trait.

Analysis of variance table refers to prescription number of days until the start of open walnuts to a highly significant statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment. Table 11 shows that the use of pesticides has led to a lack of the arithmetic average of these capacity compared with treatment that did not use the pesticide.

Analysis of variance table refers to prescription number of days and up to 50% of open walnuts to a highly significant statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment. Table 12 private arithmetic averages is clear that the use of pesticides has led to the decline of the arithmetic average of this status compared with the treatment that did not use the pesticide. Indicates table analysis of variance for prescription number walnuts total to differences statistically highly significant between arithmetic means of transactions, which have been used pesticides and treatment control and Table 13 shows that the use of pesticides has led to an increase in the arithmetic mean for this trait compared with treatment that did not use the pesticide.

Indicates table analysis of variance for prescription number walnut open-minded to the existence of differences statistically highly significant between arithmetic means of transactions, which have been used pesticides and treatment control and Table 14 for averages calculation shows that the use of pesticides has led to increased SMA this status compared with treatment that did not use the exterminator.

Analysis of variance table refers to prescription average weight of Walnut and there were statistical differences between the arithmetic mean of the transactions where pesticides have been used and the control treatment and Table 15 for arithmetic averages is clear that the use of pesticides has led to an increase compared with the treatment that did not use the pesticide.

Shows table analysis of variance for prescription rate Labatt wheat, and there are differences statistically highly

significant between arithmetic means of transactions, which have been used pesticides and treatment control and Table 27 for averages calculation shows that the use of pesticides has led to a decrease in average prescription rate germination of wheat compared with treatment that did not where the pesticide is used.

Did not show differences in plant height of the wheat crop grown in the Anvils .As was the arithmetic average of plant height and all transactions between 50-51 cm, indicating a transaction or pesticides applied in cotton crop did not affect this trait unlike prescription seed germination significantly affected by the pesticide used. The reason that the remaining pesticides at least its impact over time and that the period in which they passed the germination stage was highly effective pesticides for this affected the germination of seeds, but it did not affect plant growth vegetatively (Table 28).

CONCLUSIONS

- Not recommended the use of the pesticide the Super Vioselajd in combating the jungles of the cotton fields.
- Efficiency of pesticide appear when sprayed early, especially in hot climates.
- Active pesticide Fox Ultra toward the bushes in hot weather
- After the pesticide remains in the soil for a short period
- Cause high bushes loss estimated at 35 g 79% in the cotton fields
